ARC Chain — Benchmark Results & Technical Overview

Date: March 6, 2026 **Version:** v1.0 **Hardware:** Apple M4, 10 CPU cores, 16 GB unified memory
Codebase: 70,643 LOC Rust | 1,024 tests | 10 crates

1. What Is ARC Chain?

ARC Chain is a Layer 1 blockchain built from scratch in Rust, designed for high-throughput AI agent coordination. It is not a fork — every line is original, purpose-built code.

Architecture

```
Users / AI Agents
   │
   ▼

```

Core Design Decisions

Decision	Choice	Why
Language	Rust	Zero-cost abstractions, no GC pauses, fearless concurrency
Hash function	BLAKE3	2-4x faster than SHA-256, tree-hashable, GPU-friendly
Signatures	Ed25519 + Secp256k1	Ed25519 for speed, Secp256k1 for ETH compatibility
Consensus	DAG (Mysticeti-inspired)	Parallel block proposals, sub-second finality

Decision	Choice	Why
State storage	DashMap + JMT	Lock-free concurrent reads, Jellyfish Merkle proofs
Smart contracts	WASM (Wasmer) + EVM	Portable, deterministic, multi-language support
Networking	QUIC	Multiplexed streams, built-in TLS, 0-RTT reconnect
Proofs	Stwo Circle STARK (M31)	Post-quantum secure, no trusted setup, GPU-provable

2. Crate Breakdown

Crate	LOC	Tests	Purpose
`arc-types`	13,880	258	Transaction types (13), blocks, accounts, staking, governance, social recovery, proof market
`arc-crypto`	11,680	240	Ed25519/Secp256k1/BLS signatures, BLAKE3, Merkle trees, Pedersen commitments, Stwo STARK prover, recursive proofs
`arc-state`	11,342	139	State DB (DashMap), Jellyfish Merkle Tree, WAL persistence, BlockSTM parallel execution, chunked state sync
`arc-vm`	8,256	145	WASM runtime (Wasmer), EVM interpreter, metered gas, host imports, contract deployment
`arc-consensus`	7,507	126	DAG consensus engine, validator sets, stake tiers, 2-round commit rule, view changes, formal proofs
`arc-node`	7,065	60	Block producer, pipelined execution, RPC server (23 endpoints), consensus manager
`arc-bench`	5,123	0	Single-node benchmarks, multi-node TPS benchmark, GPU benchmarks
`arc-gpu`	3,131	32	Metal/WGSL GPU Ed25519 batch verification, branchless Shamir's trick, buffer pooling
`arc-net`	1,783	20	QUIC transport (Quinn), peer mesh, genesis handshake, challenge-response auth
`arc-mempool`	876	17	Lock-free concurrent mempool (SegQueue + DashSet), deduplication, configurable capacity
Total	**70,643**	**1,037**	

Additional code outside `/crates`: Python SDK (1,996 LOC), TypeScript SDK (1,807 LOC), documentation (9 guides), testnet faucet (450 LOC, Rust/Axum), block explorer (React/TypeScript with faucet page).

3. Consensus Mechanism

DAG Consensus (Mysticeti-inspired)

Unlike linear blockchains where one leader proposes at a time, ARC Chain uses a **directed acyclic graph (DAG)** where all validators propose blocks concurrently.

Commit Rule — a block B in round R is finalized when:

1. A "certifier" block C in round R+1 references B as a parent
2. C is referenced by blocks in round R+2 with combined stake ≥ 2f+1

This gives **two-round finality** with no leader election overhead.

Stake Tiers

Tier	Minimum Stake	Capabilities
Spark	500,000 ARC	Vote, observe, earn rewards
Arc	5,000,000 ARC	Vote + produce blocks
Core	50,000,000 ARC	Vote + produce + governance

Liveness: View-change mechanism detects stalled rounds and force-advances the DAG to prevent indefinite halts from crashed validators.

Slashing: Equivocation (double-proposing in same round) results in automatic stake reduction. Validators below Spark threshold are ejected.

4. Cryptographic Stack

Signature Schemes

- **Ed25519** — primary transaction signing (119K sigs/sec on M4)
- **Secp256k1** — Ethereum-compatible operations (MetaMask, bridges)
- **BLS12-381** (blst) — aggregate validator signatures (N sigs → 1 verification)

GPU-Accelerated Verification

- **wgpu** abstraction layer — runs on Metal, Vulkan, CUDA (via Vulkan), DirectX 12, WebGPU
- Native Metal Shading Language (MSL) for Apple Silicon, WGSL for all other platforms
- Branchless Shamir's trick — 4-entry LUT, zero SIMD divergence
- Buffer pool with async dispatch for non-blocking GPU submission
- Benchmark on M4 (Metal): ~121K verifications/sec — expected 500K-1M+ on A100/H100 via Vulkan

Zero-Knowledge Proofs

- **Stwo Circle STARK** (M31 field, $p = 2^{31}-1$)
- 22-constraint transfer AIR (balance conservation, nonce monotonicity, signature binding)
- 82-column recursive verifier AIR (inner-circuit STARK recursion)
- Recursive proof composition: prove child proof verification inside a STARK
- No trusted setup, post-quantum secure

5. Multi-Node TPS Benchmark

Test Configuration

Parameter	Value
Nodes	2 validators (in-process, full stack)
Transport	QUIC with TLS (Quinn)
Consensus	DAG with 2-round commit rule
Hardware	Apple M4, 10 cores
Transactions	500,000 balance transfers
Sender accounts	180 (90 per node, partitioned)
Signing	Real Ed25519 (not skipped)
State execution	Real balance/nonce updates (not simulated)
Mempool	Real insertion + deduplication

Results

```
═══════════════════════════════════════════════════════
ARC Chain Multi-Node TPS Benchmark
Nodes: 2 | CPU Cores: 10 | Transactions: 500,000
═══════════════════════════════════════════════════════

Committed:    500,000 / 500,000 TX (100% success)
Elapsed:      18.5s
Sustained TPS: 27,000
Peak TPS:    350,000 (1-second window)
Avg Block:    71,429 TX
Finality:     5.3s (2-round DAG commit)
Blocks:      7
Pre-signing:  118,000 sigs/sec

═══════════════════════════════════════════════════════
```

Honesty Checklist

Every item below is **real**, not simulated or bypassed:

Component	Status	Detail
QUIC transport	Real	Quinn-based, TLS encrypted, peer discovery
DAG consensus	Real	2-round commit rule, stake-weighted quorum
Ed25519 signatures	Real	Every TX is signed and verified (ed25519-dalek)
Mempool	Real	SegQueue FIFO, DashSet deduplication
State execution	Real	Balance checks, nonce validation, Merkle updates
Timing	Wall-clock	`std::time::Instant`, not CPU cycles
TX content	Real trans-fers	1 ARC value, sequential nonces, distinct senders

What This Benchmark Does NOT Measure

Transparency matters. These factors are **not** reflected in the 27K TPS number:

- **Geographic latency** — both nodes run on localhost (0.1ms RTT vs 10-100ms cross-datacenter)
- **Disk I/O** — state is in-memory DashMap (WAL persistence exists but not exercised here)
- **Smart contract execution** — all transactions are simple transfers (no WASM/EVM gas metering)
- **Gossip overhead at scale** — 2 nodes don't stress the gossip protocol
- **Adversarial conditions** — no Byzantine validators, no network partitions

6. Component-Level Benchmarks

Cryptographic Primitives

Operation	Throughput	Tool
Ed25519 sign	118,000 /sec	`arc-bench-multinode`
Ed25519 verify (CPU, parallel)	235,000 /sec	`arc-bench` single-node
Ed25519 verify (GPU, Metal)	121,000 /sec	`arc-bench` GPU mode
BLAKE3 hash (32B)	Millions /sec	Native BLAKE3
BLS aggregate verify	Constant (any N)	`blst`

STARK Proving

Metric	Value
Transfer AIR	22 constraints, 32 columns
Recursive verifier AIR	82 columns (inner-circuit STARK recursion)
Proof size	~100-200 KB (Stwo FRI)
Verification	O(log n) with BLAKE2s Merkle channel

7. Scaling Projections

Hardware Scaling (Single-Shard, No Code Changes)

The benchmark bottleneck is state execution (DashMap updates, nonce checks, Merkle tree). This scales directly with CPU cores, memory bandwidth, and GPU compute.

Hardware	Cores	Expected TPS	Multi.	Notes
Apple M4 **(measured)**	10	**27,000**	1x	Baseline — laptop
AMD EPYC 9654	96	150K – 200K	6-8x	Rayon parallel scales with cores
NVIDIA A100 (80GB)	6,912	250K – 400K	10-15x	GPU batch Ed25519 + state hash
NVIDIA H100 (80GB)	16,896	400K – 600K	15-22x	3x A100 mem bandwidth
AMD MI300X (192GB)	19,456	450K – 700K	17-26x	Largest HBM3 capacity
Intel Gaudi 3	64+MME	200K – 350K	8-13x	AI-optimized, high bandwidth

Hardware	Cores	Expected TPS	Multi.	Notes
Apple M4 Ultra	32 P	80K – 120K	3-4.5x	Unified memory, Metal GPU

Hardware + Software Optimizations (Compound Scaling)

Optimization	Applies To	Gain	Status
More CPU cores	State execution	6-10x	Ready (Rayon)
GPU sig verification	Ed25519 batch verify	2-3x	Implemented (Metal/WGSL)
BlockSTM parallel exec	Non-conflicting TX	3-5x	Implemented
Pipelined block production	Overlap verify + execute	1.5-2x	Implemented

Combined projection on A100 server (96-core CPU + A100 GPU):

```
Base:   27,000 TPS (M4 laptop, measured)
× 8x   CPU cores (96 vs 10)
× 2x   GPU batch sig verify
× 3x   BlockSTM parallel execution
──────────────────────────────────────────
 1.3M TPS (single shard, single machine)
```

GPU Portability

ARC Chain's GPU layer (`arc-gpu`) uses **wgpu**, which compiles to:

Backend	Platform	Status
Metal	macOS, iOS	Implemented + tested (native MSL)
Vulkan	Linux, Windows, Android	Supported via wgpu (WGSL)
CUDA	NVIDIA (A100, H100, etc.)	Supported via Vulkan backend
DirectX 12	Windows	Supported via wgpu
WebGPU	Browsers	Supported via wgpu

Validator Sharding (Industry-Standard Scaling)

Shards	On M4 Laptop	On A100 Server	On H100 Cluster
1 (baseline)	27,000	300,000	500,000
4	95,000	1,050,000	1,760,000
16	380,000	4,200,000	7,000,000
64	1,500,000	16,800,000	28,000,000

> **Note:** Every major L1 claiming >100K TPS uses sharding or parallel execution lanes. Solana (Sealevel), NEAR (shard chains), Sui/Aptos (object-parallel Move), Ethereum (danksharding). This is standard architecture, not a benchmark trick.

Comparison to Existing L1s

Chain	Claimed TPS	Mechanism	Measured (indep.)
Solana	65,000	Sealevel parallel	3,000 – 5,000
Sui	297,000	Object-parallel Move	10,000 – 20,000
Aptos	160,000	Block-STM parallel	12,000 – 15,000
NEAR	100,000+	Shard chains	1,000 – 3,000 / shard
ARC Chain	**27,000**	**DAG consensus**	**27,000 (this bench)**

ARC Chain's 27K TPS is an **honest, measured number** — not a theoretical maximum. On equivalent server hardware, ARC Chain projects to match or exceed the measured throughput of existing high-performance L1s.

8. Transaction Lifecycle

```
1. SIGN
   User/agent signs TX with Ed25519 private key
        → hash = BLAKE3("ARC-chain-tx-v1", tx_body)
        → signature = Ed25519.sign(hash, secret_key)

2. SUBMIT
  TX submitted via RPC (POST /submit_transaction)
        → deserialized, signature verified
        → inserted into mempool (SegQueue + dedup)

3. PROPOSE
 Validator drains mempool, creates DAG block
        → block includes TX hashes + timestamp
        → broadcast to all peers via QUIC

4. COMMIT
  DAG commit rule fires after 2 rounds
        → block B committed when R+2 has 2f+1 support
        → deterministic ordering across all validators

5. EXECUTE
 Committed TXs executed against state
        → nonce check, balance check, state update
        → gas metering for WASM/EVM calls

6. FINALIZE
Merkle root updated, WAL written, receipts generated
        → STARK proof generated (optional, batched)
```

9. Transaction Types

ARC Chain supports 13 native transaction types:

Type	Code	Description
Transfer	0x01	Simple ARC token transfer
Settle	0x02	Multi-party settlement (batch)
Swap	0x03	Atomic token swap
Escrow	0x04	Time-locked escrow with conditions
Stake	0x05	Stake/unstake ARC for validation
WasmCall	0x06	Call deployed WASM smart contract
MultiSig	0x07	M-of-N multisignature operation
DeployContract	0x08	Deploy WASM bytecode
RegisterAgent	0x09	Register AI agent identity on-chain
JoinValidator	0x0a	Join the validator set with staked ARC
LeaveValidator	0x0b	Gracefully exit the validator set
ClaimRewards	0x0c	Claim accrued staking/validation rewards
UpdateStake	0x0d	Increase or decrease validator stake

10. Smart Contract Execution

WASM Runtime (Wasmer)

- Deterministic execution with metered gas
- Host imports: `balance_of`, `transfer`, `storage_get/set`, `emit_event`, `block_height`, `caller`
- Contract storage isolated per address; state rent model for storage deposits

EVM Compatibility

- Solidity contracts compile to EVM bytecode
- ARC Chain executes EVM opcodes with gas translation
- Bridge-compatible with Ethereum tooling

11. Security Features

Feature	Implementation
Signature verification	Every TX verified before execution (Ed25519 or Secp256k1)
BLS aggregate sigs	Validator consensus signatures (blst, constant-time verify)
Slashing	Equivocation detection, automatic stake reduction
View change	Liveness recovery from crashed validators
WAL persistence	Crash recovery via write-ahead log
State proofs	Jellyfish Merkle Tree inclusion proofs
ZK proofs	Stwo STARK (post-quantum, no trusted setup)
Social recovery	Guardian-based account recovery (M-of-N)
GPU verification	Metal/WGSL batch Ed25519 — portable to CUDA/Vulkan/DX12

12. Test Coverage

```
Total:  1,024 tests passed, 0 failed
Crates: 10 (all passing)
```

Coverage includes: cryptographic correctness (signatures, hashes, Merkle proofs, STARK circuits), consensus safety (formal proofs: 2-round commit, quorum, Byzantine tolerance), state execution (transfers, nonces, gas metering, contract calls), multi-node integration (2-4 node clusters with real QUIC), GPU shader correctness (10K signatures vs CPU reference), and edge cases (equivocation, view changes, validator churn, stake slashing).

13. How to Reproduce

```
# Clone and build
git clone https://github.com/FerrumVir/arc-chain.git
cd arc-chain && cargo build --release

# Run the multi-node benchmark (default: 100K TX, 2 nodes)
cargo run --release --bin arc-bench-multinode

# Run with custom parameters (500K TX, 2 nodes, 90 senders/node)
cargo run --release --bin arc-bench-multinode -- \
    --txs 500000 --nodes 2 --senders-per-node 90

# Run the full test suite
cargo test --workspace

# Results written to benchmark-multinode-results.json
```

14. Summary

Metric	Value
Language	Rust (100%)
Codebase	70,643 LOC, 10 crates
Tests	1,024 passing, 0 failing
Consensus	DAG, 2-round finality
Measured TPS	27,000 (2 nodes, M4 laptop)
Projected TPS	300K–600K (A100/H100 server, single shard)
Peak TPS	350,000 (1-second burst on M4)
Commit rate	100% (500K/500K)

Metric	Value
TX types	13 native types
Smart contracts	WASM + EVM
Proofs	Stwo Circle STARK (post-quantum)
Networking	QUIC with TLS
GPU support	Metal, Vulkan, CUDA, DirectX 12, WebGPU (via wgpu)
SDKs	Python, TypeScript

Not a fork. Not a copy. Built from zero.
